Comparing roller screws to ball screws

The load carrying capacity of a rolling screw depends practically on the surfaces at the points of contact:

- their diameter
- the number of contacts
- their hardness
- their surface finish
- the precision of the contacts to assure load sharing between them.

Ball screws

In ball screws, the load is transmitted from the nut to the shaft through the balls engaged in the groove.

In a single start ball screw, the ball diameter is limited to approximately 70 % of the lead: there is only a single helix of balls in a nut of given length so the number of contacts is small.

Roller screws

In roller screws, the load is transmitted from the nut to the shaft through the barrelled surfaces of all the engaged rollers.

The diameter of the contact surface is substantially increased as is the number of points of contact.

2 types of roller screws

Planetary roller screw
Threaded rollers are the basis of "SR / BR / TR / PR" planetary roller screws.

Recirculating roller screw
Grooved rollers are the basis of "SV / BV / PV" recirculating roller screws.

Extended life

Minimum maintenance costs

More reliable operation

Break out from the limitations of ball screw performance

The 10 reasons for using roller screws

- High load ratings (SR-SV)
- Very high rotational speed (SR)
- High acceleration and deceleration rates (SR)
- Long life at high cycling rates (SR)
- High reliability (SR-SV)
- Resistance to hostile surroundings (SR)
- Ability to survive shock loads (SR)
- Small displacements with very good repeatability (SV)
- Rotating the nut when speed becomes critical (SR)
- Frequently removing the nut from the screw shaft (SR-most SV).

The principle of planetary roller screws

fig. 1

Threaded rollers are the basis of SR/BR/TR/PR planetary roller screws.

The specific qualities of SKF planetary roller screws

Many strong contact surfaces	High load carrying capacity	Long life
No recirculation and no contact between rolling elements	No weak points in the nut High rotation speed	Less fatigue Robust & shock resistant
Guided rollers	No loss in preload torque when changing direction	Smooth running
Timing mechanism	Exceptional reliability	Ability to work with ice, dirt or poor lubrication
Adaptable tooling	Non standard and left hand leads available	Tailor-made

All parts made “in house”, special steels possible

Typical applications

The capacity to carry heavy loads for thousands of hours in the most arduous conditions makes SR/BR/TR/PR planetary roller screws suitable for the most demanding applications. The robust nut can withstand shock loads and the timing mechanism ensures reliability even in harsh environments and at high accelerations; the long lead and the symmetrical design of the nut permit high linear speeds.

Examples:

- Plastic molding.
- Broaching machines.
- Valves.
- Presses
- Machine tools.
- The steel industry.
- The tyre industry.
- Automatic handling.
- Military aircraft, tanks, rocket launchers, radar, ships and submarines.
- The nuclear industry.

The principle of recirculating roller screws

fig. 1
Grooved rollers are the basis of SV/BV/PV recirculating roller screws.

The specific qualities of SKF recirculating roller screws

Very small leads (1mm)	Fine resolution	Minimum drive torque	High mechanical advantage
No miniature parts	Simple	Robust	Reliable
Many strong contact points	Heavy load carrying capacity	High rigidity	Long life
All parts made "in house", special steels possible			

Typical applications

Ultimate positioning accuracy can be obtained using the fine lead of SV/BV/PV recirculating roller screws. Their great mechanical advantage minimizes input torque and increases resolution. They can simplify a complete transmission and improve its rigidity. They are often used in applications of advancing technology where reliable optimum performance is vital.

Examples:

- Grinding machines
- Laboratory equipment.
- Hospital equipment.
- Paper making
- The printing industry
- Telescopes
- Satellites

Recommendations for selection

Only basic selection parameters are included. To make the very best selection of a roller screw, the designer should specify such critical parameters as the load spectrum, the linear or rotational speed, the rates of acceleration and deceleration, the cycle rate, the environment, the required life, the lead accuracy, the stiffness, and any special requirement. If in doubt, please consult an SKF specialist before placing an order.

Basic dynamic load rating (C_a)

The dynamic rating is used to compute the fatigue life of roller screws. It is the axial load constant in magnitude and direction, and acting centrally under which the nominal life (as defined by ISO) reaches one million revolutions.

Nominal fatigue life L_{10}

The nominal life of a roller screw is the number of revolutions (or the number of operating hours at a given constant speed) which the roller screw is capable of enduring before the first sign of fatigue (flaking, spalling) occurs on one of the rolling surfaces (screw, nut or roller thread or groove).

In cases where more than 90 % probability of a screw attaining or exceeding its life is required.

% reliability	Adjusted life
90 %	$1,00 \times L_{10}$
95 %	$0,62 \times L_{10}$
96 %	$0,53 \times L_{10}$
97 %	$0,44 \times L_{10}$
98 %	$0,33 \times L_{10}$
99 %	$0,21 \times L_{10}$

It is however evident from both laboratory tests and practical experience that seemingly identical roller screws operating under identical conditions have different lives, hence the notion of *nominal life*.

It is, in accordance with ISO definition, the life achieved or exceeded by 90 % of a sufficiently large group of apparently identical roller screws, working in identical conditions (alignment, axial and centrally applied load, speed, acceleration, lubrication, temperature and cleanliness).

Service life

It is the actual life achieved by a specific roller screw before it fails. Failure is not only by fatigue (flaking or spalling); but also by inadequate lubrication and wear; wear of the recirculation system, corrosion, contamination, and, more generally, by loss of the functional characteristics required by the application.

Experience acquired with similar applications will help to select the proper screw to obtain the required service life. Also, one must take into account structural requirements such as the strength of screw ends and nut attachments, due to the loads applied on the elements in service. To attain L_{10} life performance a mean working load of up to 80 % of C_a is permitted.

Life test bench

(1) SKF can help you to define this value in relation with the actual conditions of service.

Equivalent dynamic loads

The loads acting on the screw can be calculated according to the laws of mechanics if the external forces (e.g. power transmission, work, rotary and linear inertia forces) are known or can be calculated. It is necessary to calculate the equivalent dynamic load (see page 76).

Radial and moment loads must be taken by linear bearing systems. It is extremely important to resolve these problems *at the earliest conceptual stage*. These forces are detrimental to the life and the expected performance of the screw.

Fluctuating load

When the load fluctuates during the working cycle, it is necessary to calculate the equivalent dynamic load: this load is defined as that hypothetical load, constant in magnitude and direction, acting axially and centrally on the screw which, if applied, would have the same influence on the screw life as the actual loads to which the screw is subjected.

Additional loads due, for example to misalignment, uneven loading, shocks, and so on, must be taken in account.

Their influence on the nominal life of the screw is generally taken care of, consult SKF for advice.

Static load carrying capacity (C_{0a})

Roller screws should be selected on the basis of the static load rating C_{0a} instead of on life when they are submitted to continuous or intermittent shock loads, while stationary or rotating at very low speed for short duration.

The permissible load is determined by the permanent deformation caused by the load acting at the contact points.

It is defined by ISO standards as the purely axially and centrally applied static load which will create, by calculation, a total (rolling element + thread surface) permanent deformation equal to 0.0001 of the diameter of curvature of the rolling element. This deformation corresponds to a contact Hertz stress up to 4500 MPa depending on the screw diameter.

The roller screw must be selected by its basic static load rating which must be, at least, equal to the product of the maximum axial static load applied and a safety factor " s_0 ".

The safety factor is selected in relation with past experience of similar applications and requirements of running smoothness and noise level (1).

Critical rotating speed for screw shafts

The shaft is equated to a cylinder the diameter of which is the root diameter of the thread. The formulas (see page 76) use a parameter the value of which is dictated by the mounting of the screw shaft (whether it is simply supported or fixed).

As a rule the nut is not considered as a support of the screw shaft. Because of the potential inaccuracies in the mounting of the screw assembly, a safety factor of 0.80 is applied to the calculated critical speeds.

Calculations which consider the nut as a support of the shaft, or reduce the safety factor, require practical tests and possibly an optimization of the design (1).

(1) SKF can help you to define this value in relation with the actual conditions of service.

Permissible speed limit

The permissible speed limit is that speed which a screw cannot reliably exceed at any time. It is generally the limiting speed of the centrifugal forces in the nut. It is expressed as the product of the rpm and the diameter of the screw shaft (in mm).

The speed limits quoted in this catalogue (see page 76) *are the maximum speed that may be applied through very short periods* and in optimized running conditions of alignment, light external load and preload with monitored lubrication.

Running a screw continuously at the permissible speed limit may lead to a reduction of the calculated life of the nut mechanism.

High speed associated with high load requires a large input torque and yields a relatively short nominal life (1).

In the case of high acceleration and deceleration, it is recommended to either work under a nominal external load or to apply a light preload to the nut to avoid internal sliding during reversal.

The value of the preload of screws submitted to high acceleration is that preload which ensures the rolling elements do not slide (1).

Too high a preload will create unacceptable increases of the internal temperature.

Lubrication

The key point is the initial lubrication of the nut to lubricate all components. The lubrication of screws rotating at high speed must be properly considered in quantity and quality.

The volume, spread and frequency of the application of the lubricant (oil or grease) must be properly selected and monitored. At high speed the lubricant spread on the surface of the screw shaft may be thrown off by centrifugal forces. It is important to monitor this phenomenon during the first run at high speed and possibly adapt the frequency of re-lubrication or the flow of lubricant, or select a lubricant with a higher viscosity.

Monitoring the steady temperature reached by the nut permits the frequency of re-lubrication or the oil flow rate to be optimized.

Oil lubrication

A centralised recirculating oil system is ideal because it continuously changes the oil in the nut with cooled filtered oil from the reservoir. This system is prescribed when the temperature is likely to affect the positioning accuracy. The flow of oil can be regulated to optimise film thickness and removal of heat.

Selection of oil

Mineral oil normally used to lubricate other rotating parts such as bearings and gears may be used for the screw. The viscosity of the oil is defined by the speed, running temperature and load. The oil should have a viscosity of 100 ISO at the running temperature. An increase in viscosity or speed will increase the running temperature. At low speed (< 10 rpm) the viscosity should be 200 ISO at the running temperature. Under heavy load an EP additive to improve the film strength is recommended. Corrosion resistant and stabilizing additives may also be used to advantage.

Synthetic oils (PAO, ester) are advised for long life, high temperature.

Barium soap is advised under heavy load, low speed and when adhesion is required.

(1) SKF can help you to define this value in relation with the actual conditions of service.

Grease lubrication

Where oil lubrication is not practicable, the grease recommended for the support bearings of the screw may also be used for the screw.

After a few full strokes the grease will be spread evenly over the useful threaded length of the screw shaft, which will also help to protect the screw against corrosion. However the grease is open to the air.

To prevent dirt which may fall on it from entering the nut, wipers should be mounted in each end of the nut. Also the grease on the screw shaft will age more quickly than that in the screw support bearings so more frequent regreasing is needed, especially in a dirty environment. If the screw cannot be dismounted and cleaned before regreasing it is necessary to thoroughly clean the old grease from the screw shaft. This can be done with a spatula and then with a clean fluff proof cloth. To clean even more a cloth wetted with a solvent such as white spirit may be used. We do not advise using brushes to remove old or spread new grease (risk of bristles coming out). Apply also the new grease through the nut to push out the old from inside the nut.

The grease type is defined above all by the operating temperature, environment and load on the screw.

Speed, starting torque and chemical compatibility may also be taken into consideration.

Normally bearing greases of NLGI consistency 2 are used. A grease which is too hard at low temperature may restrict rotation or one which is too soft at high temperature may run off.

Selection of grease

Lithium base greases, for standard applications with EP-additives, are generally suitable for use from $-30\text{ }^{\circ}\text{C}$ to $+110\text{ }^{\circ}\text{C}$.

A few can be used to $+150\text{ }^{\circ}\text{C}$. Lithium base greases are virtually insoluble in water and very work stable. However they absorb large quantities of water when worked to extremes.

Lubrication interval

The lubrication interval depends on the working cycle of the screw and whether the lubricant is polluted during use. General advice is difficult but the following will help you to define the interval. On start up check the grease quality regularly, for instance every month.

The first re-lubrication has to be done after roughly 50 000 revolutions under load, to remove all particles generated during deburring.

If the viscosity of the grease sample has increased, it needs replacing.

If the grease sample is darker than new it may indicate oxidation or the presence of metallic particles.

If it is discoloured, it is probably mixed with water.

It is helpful to take samples not only from the part of the screw where running has occurred but also from unused parts of the screw where the grease acts as corrosion preventer.

(1) SKF can help you to define this value in relation with the actual conditions of service.

Quantity of lubricant

• Oil

We advise a quantity of $5 > 25 \text{ cm}^3/\text{h}$ in shots of $0,1 \text{ cm}^3$ as an order of magnitude depending on the size of the screw and its running conditions.

• Grease

The total volume of grease needed for a new roller screw is the sum of the quantities needed for the screw shaft and the nut.

The volume of grease necessary for the screw shaft Z_s can be estimated from this formula:

$$Z_s = 4,4 \times 10^{-4} d_0 l_1$$

This quantity of grease should be spread over the whole threaded length of the shaft. The volume of grease for the nut Z_n is one third of the free volume in the nut.

The quantity Z_n is given in the dimension tables: it should be injected through the lubrication hole while turning the shaft.

Before applying load the nut should be run twice along the complete stroke to ensure grease is evenly spread.

Relubrication, see also 'Grease lubrication'

In the case of the existing grease being polluted, remove as much of it as possible and apply the same quantity as when first lubricated.

If the existing grease is clean add a volume $Z_n / 3$ into the nut. Generally speaking, it is better to inject small quantity frequently than the contrary.

Efficiency and back-driving

The performance of a screw is mainly dependant on the geometry of the contact surfaces and their finish as well as the helix angle of the thread.

It is, also, dependant on the working conditions of the screw (load, speed, lubrication, preload, alignment, etc...).

The "direct efficiency" is used to define the input torque required to transform the rotation of one member into the translation of the other. Conversely, the "indirect efficiency" is used to define the axial load required to transform the translation of one member into the rotation of the other one. It is used, also, to define the braking torque required to prevent that rotation.

These screws are reversible or back-driveable under almost all circumstances. It is therefore necessary to design a brake mechanism if backdriving is to be avoided (gear reducers or brake).

Preload torque:

Internally preloaded screws exhibit a torque due to this preload. This persists even when they are not externally loaded. Preload torque is measured at 50 rpm when assembly is lubricated with ISO grade 64 oil.

Starting torque:

This is defined as the torque needed to overcome the following to start rotation:

- a) the total inertia of all moving parts accelerated by the energy source (including rotation and linear movement).
- b) the internal friction of the screw/nut assembly, bearing and associated guiding devices.

In general, torque to overcome inertia (a) is greater than friction torque (b).

The coefficient of friction of the high efficiency screw when starting μ_s is estimated at up to double the dynamic coefficient μ , under normal conditions of use.

(1) SKF can help you to define this value in relation with the actual conditions of service.

Axial play and preload

Preloaded nuts are subject to much less elastic deformation than non-preloaded nuts.

Therefore they should be used whenever the accuracy of positioning under load and stiffness are important.

Preload, preload torque and rigidity

When a roller screw with a whole nut with axial play is measured on a tensile testing machine, a graph similar to (fig. 1) is obtained. One objective of preloading is to eliminate the axial play so that positioning accuracy is improved when the external load changes direction.

Planetary roller screws are available with play elimination using full nut (designation: BR) or split nut (designation: TR).

In this case the preload torque will be between 0 and T_{pe} measured at 50 rpm when lubricated with ISO grade 68 oil.

Planetary and recirculating roller screws are also available preloaded for optimum rigidity: their designations are PR and PV. (fig. 2) shows how a squeeze load F_q is applied to the nut halves 1 and 2 of a split nut to obtain a preload F_{pr} . One part of this load is used to generate the preload force and the other one to squeeze the spacer.

The preload spacer is ground to give the correct preload torque when the specified squeeze load is applied. Before the external load is applied the two nut halves are in equilibrium at A (fig. 4) under a load F_{pr} .

When an external load F (fig. 3) is applied the loads on the nut halves become F_1 and F_2 .

For all conditions where $F \leq 2,83 F_{pr}$ the load seen by nut half 2 is greater than the external load so increasing the preload reduces the life of the screw. When the external load reaches $2,83 F_{pr}$ nut half 1 is unloaded and $F_2 = F$. Roller screws are normally preloaded by preloading one nut half against the other so only one half supports the external load in a given direction. In this case, nut half 2 is taking the external load. The load carrying capacity and rigidity of a split preloaded nut are substantially less than a whole nut.

Because of the very high load capacity and rigidity of roller screws a split nut is sufficient for most applications and offers an extremely compact design.

fig. 1

fig. 2

fig. 3

fig. 4

Figure 5 compares the load/deflection characteristics of three different nut combinations:

Curve 1. Whole nut with axial play

Curve 2. Preloaded split nut

Curve 3. Preloaded double nut.

Backlash elimination can be achieved by fitting oversize rollers in one-piece nut (BRC-BVC) which allows to keep high load capacities.

In exceptional cases where the load rating of a split nut is not sufficient two whole cylindrical nuts may be preloaded together (fig. 6). Exact dimensions are available on request: please contact SKF.

The squeeze load applies a compressive preload in all cases: this ensures more rigidity of the roller screw compared to a preload in extension.

Preload torque is the torque resulting from the preload, F_{pr} . The preload torque is calculated from the nominal preload assuming a real efficiency of 90 % of the theoretical direct efficiency (page 77).

The preload torque,

$$T_{pr} = \frac{F_{pr} P_h 10^{-3}}{\pi} \left(\frac{1}{\eta_p} - 1 \right)$$

fig. 5

fig. 6

Preload torque tolerances

For each roller screw, preloaded for optimum rigidity a range of value of preload torque, T_{pr} is given in the technical data. The customer is free to choose any value in this range: if no value is specified on the order the mean value will be taken. A typical preload torque graph is shown on page 18: they can be obtained on request when ordering.

The reference R_{nr} value of rigidity correspond to this mean preload torque value.

The tolerance of variation of preload torque as the nut moves along the length of the screw depends on the helix angle of the screw thread, the slenderness of the screw shaft and the lead precision. The tables give the tolerances of preload torque variation. Refer to A if the helix angle, θ is less than 11° and B if it is more.

Preload torque is measured at 50 rpm with ISO grade 68 oil for SR/TR/PR screws and with ISO grade 220 oil for SV/PV screws.

A. Tolerance of preload torque for screws with $\theta < 11^\circ$

Tpr Nm	$l_1/d_0 \leq 40$ and $l_1 \leq 4000$			$l_1/d_0 \leq 60$ and $l_1 \leq 4000$		
	G1 $\pm\%$	G3	G5	G1	G3	G5
$\leq 0,2$	35	40	50	40	50	60
(0,2) - 0,6	25	30	35	30	35	40
(0,6) - 1,0	20	25	30	25	30	35
(1,0) - 2,5	15	20	25	20	25	30
(2,5) - 6,3	10	15	20	15	20	25
(6,3) - 10,0	10	10	15	15	15	20

B. Tolerance of preload torque for screws with $\theta \geq 11^\circ$

Tpr Nm	$l_1 \leq 2000$		$2000 \leq l_1 \leq 4000$	
	G3 $\pm\%$	G5	G3	G5
0 - 10,0	70	80	80	90

Planetary roller screws preloaded for optimum rigidity with $\theta \geq 11^\circ$ are not available in G1 lead precision.

Example:

A PRK 48 × 10 with threaded length 600 mm. The range of preload torque is 1,24 > 2,47 Nm. What is the tolerance of preload torque for G3 lead precision ?

The minimum guaranteed nut rigidity is 760 N/μm and the reference value is 980 N/μm. To obtain these the mean value of preload torque is specified: 1,855 Nm. The helix angle Ø is 3,79°.

Table A gives ±20 % for G3. All screws will be within the tolerance 1,855 ±20 % or 1,484 > 2,226 Nm.

If for reasons of motor torque limitations the minimum preload torque 1,24 Nm is chosen. The tolerance becomes 1,24 ±20 % or 0,99 > 1,49 Nm and the preload and minimum guaranteed and reference values of rigidity are not valid.

Two typical examples are shown.

fig. 1

fig. 2

Preload test bench

Static axial stiffness of a complete assembly

It is the ratio of the external axial load applied on the system and the axial displacement of the face of the nut in relation with the fixed (anchored) end of the screw shaft. The inverse of the *rigidity of the total system* is equal to the sum of all the inverses of the rigidity of each of the components (screw shaft, nut as mounted on the shaft, supporting bearing, supporting housings, etc...).

$$\frac{1}{R_t} = \frac{1}{R_s} + \frac{1}{R_n}$$

Because of this, the rigidity of the total system is always less than the smallest individual rigidity.

Nut rigidity: R_n

When a preload is applied to a split nut, firstly, the internal play is eliminated, then, the Hertzian elastic deformation increases as the preload applied so that the overall rigidity increases.

The theoretical deformation does not take into account machining inaccuracies, actual sharing of the load between the different contact surfaces, the elasticity of the nut and of the screw shaft. The practical stiffness values given in the catalogue are lower than the theoretical values for this reason.

They are determined by SKF based on the value of the selected basic preload and an external load equal to twice this preload.

Shaft rigidity: R_s

The elastic deformation of screw shaft is proportional to its length and inversely proportional to the square of the root diameter.

According to the relative importance of the screw deformation (see rigidity of the total system), too large an increase in the preload of the nut and supporting bearings yields a limited increase of rigidity and notably increases the preload torque and therefore the running temperature.

Consequently, the preload stated in the catalogue for each dimension is optimum and should not be increased.

$$R_s = 165 \frac{d_2^2}{l} \text{ (N/}\mu\text{m)}$$

for standard steel
see fig. 1

$$R_s = \frac{165 d_2^2 l}{l_2 (l - l_2)}$$

for standard steel
see fig. 2

fig. 1

fig. 2

Screw shaft buckling

The column loading of the screw shaft must be checked when it is submitted to compression loading (whether dynamically or statically).

The maximum permissible compressive load is calculated using the Euler formulas. It is then multiplied by a safety factor of 3 to 5, depending on the application.

The type of end mounting of the shaft is critical to select the proper coefficients to be used in the Euler formulas.

When the screw shaft comprises a single diameter, the root diameter is used for the calculation. When the screw comprises different sections with various diameters, calculations become more complex (1).

(1) SKF can help you to define this value in relation with the actual conditions of service.

Materials and heat treatments

Standard screw shafts are machined from pretreated 42 CrMo4.

Tensile strength, 850 MPa
MPa

Yield stress 650 Mpa up to
(Rp 0,2 %) 12,5 mm
radially from
outside.
550 MPa more
than 12,5 mm
radially from
outside.

Then the Transrol thread is surface hardened by induction.

Standard nuts are machined in 100Cr6 steel which is through hardened. Hardness of the contact surfaces is 56-60 HRC.

Most assemblies made of stainless material have a surface hardness in the range 42 to 58 HRC: the load rating of the catalogue therefore must be derated respectively to C'_a and C'_{oa} of C'_a and C'_{oa} being the capacities with the new hardness in Vickers (Hv).

$$C'_a = C_a \times \left(\frac{H_v}{654} \right)^2$$

$$C'_{oa} = C_{oa} \times \left(\frac{H_v}{654} \right)^3$$

fig. 1

Through hardening treatment

Working environment

Our products have not been developed for use in an explosive atmosphere, consequently we cannot take any responsibility for their use in this field.

NOTE: 42 CrMo4, an AFNOR reference is similar to AISI 4140; 100Cr6 is similar to AISI 52100.

Induction hardening

Shaft Design

It is possible to deliver roller screws with *one* end larger than the outside diameter, d_1 of the shaft. To grind the thread efficiently an undercut at root diameter d_2 and length l_2 is needed (fig. 1).

Zone A. Torsion only

The nominal shear stress τ caused by the drive torque T is given by:

$$\tau = \frac{16 T}{\pi d_5^3}$$

This is increased by a stress concentration factor f_4 to give the real shear stress, τ_p

$$\tau_p = f_4 \tau$$

According to Von Mises the total stress, σ_t

$$\sigma_t = 1,73 \tau_p$$

For safety σ_t should be less than 67 % of the 0,2 % proof stress of the steel.

If the end diameter d_5 includes a keyway of depth e calculate with $(d_5 - e)$.

The angle of twist of the screw shaft is given by

$$\theta = \frac{0,0648 T l}{d_o^4}$$

The linear positioning error, δ , caused by this twist

$$\delta = \frac{P_h \theta}{360}$$

Zone B. Axial + torsional stresses

The nominal axial stress caused by the axial load F is given by

$$\sigma = \frac{4F}{\pi d_4^2}$$

This is increased by a stress concentration factor f_5 to give the real principal stress σ_p

$$\sigma_p = f_5 \sigma$$

as above

$$\tau_p = f_4 \tau$$

According to Von Mises the total stress σ_t

$$\sigma_t = (\sigma_p^2 + 3 \tau_t^2)^{1/2}$$

For safety σ_t should be less than 67 % of the 0,2 % proof stress of the steel.

fig. 1

Strength of machined ends

The end machining of a roller screw is designed by the customer. Due to the high static and dynamic load ratings of roller screws it is important to check the strength of the machined ends.

This checking must be your responsibility unless you specifically ask SKF.

This simple approach takes into account the different diameters of the end where stress concentration factors must be used: it takes into consideration only axial and torsional stresses.

Nota: Stress concentration factors f_4 and f_5 are available in all general mechanical literature.

Manufacturing precision

Generally speaking, the precision indication given in the designation defines the lead precision: see page 24.

Lead precision according to ISO (ex. G1 - G5...).

Parameters other than lead precision correspond to our internal standards (generally based on ISO 3408-3 class 5).

If you require special tolerances (for example class 1 or 3) please specify when requesting a quotation or ordering.

Inspection of surface finish

Lead error control interferometric test bench

Recommended assembly procedure

Roller screws are precision components and should be handled with care to avoid shocks. When stored out of the shipping crate they must lie on wooden or plastic vee blocks and should not be allowed to sag.

Screw assemblies are shipped in a cardboard/wooden crate, wrapped in a sealed plastic bag which protects them from foreign material and possible pollution. They should stay wrapped until they are used.

Radial and moment loads

Any radial or moment load on the nut will overload some of the contact surfaces, thus significantly reducing its life. (fig. 1)

Alignment

SKF linear guidance components should be used to ensure correct alignment and avoid non-axial loading. The parallelism of the screw shaft with the guiding devices must be checked.

If external linear guidance prove impractical, we suggest mounting the nut on trunnions or gimbals and the screw shaft in self-aligning bearings.

Mounting the screw in tension helps align it properly and eliminates buckling.

Lubrication

Good lubrication is essential for the proper functioning of the screw and for its long term reliability (1), (see fig. 2).

Before shipping, the screw is coated with a protective fluid that dries to a film. *This protective film is not a lubricant.*

Depending on the selected lubricant, it may be necessary to remove this film before applying the lubricant (there may be a risk of non-compatibility).

If this operation is performed in a potentially polluted atmosphere it is highly recommended to proceed with a thorough cleaning of the assembly.

Designing the screw shaft ends

Generally speaking, when the ends of the screw shaft are specified by the customer's engineering personnel, it is their responsibility to check the strength of these ends.

Roller screws can be supplied with one end bigger than the diameter of the threaded portion. The core strength of such an end may be affected by large reductions of diameter. When this concept of a large end is used, a minimum length at root diameter is needed between the end of the thread and the face of the larger diameter.

Starting-up the screw

After the assembly has been cleaned, mounted and lubricated, it is recommended that the nut is allowed to make several full strokes at low speed; to check the proper positioning of the limit switches or reversing mechanism before applying the full load and the full speed.

Operating temperature

Screws made from standard steel (see page 20) and operating under normal loads can sustain temperatures in the range $-20\text{ }^{\circ}\text{C}$ to $+110\text{ }^{\circ}\text{C}$.

Between $110\text{ }^{\circ}\text{C}$ and $130\text{ }^{\circ}\text{C}$, SKF must be notified so that it adapts the annealing procedure and checks that the application can be successful with a hardness below the standard minimum value.

Above $+130\text{ }^{\circ}\text{C}$ Celsius, steels adapted to the temperature of the application should be selected, which could decrease the load rating.

Consult SKF for advice.

NOTE:

Operating at high temperature will lower the hardness of the steel, alter the accuracy of the thread and may increase the oxidability of the materials.

fig. 1

fig. 2

(1) SKF can help you to define this value in relation with the actual conditions of service.

Lead precision according to ISO

Lead precision is measured at 20 °C on the useful stroke l_u , which is the threaded length decreased, at each end, by the length l_e equal to the screw shaft diameter.

V_{300p} μm	G1 6		G3 12		G5 23	
l_u mm	e_p μm	v_{up}	e_p	v_{up}	e_p	v_{up}
0 - 315	6	6	12	12	23	23
(315) - 400	7	6	13	12	25	25
(400) - 500	8	7	15	13	27	26
(500) - 630	9	7	16	14	32	29
(630) - 800	10	8	18	16	36	31
(800) - 1000	11	9	21	17	40	34
(1000) - 1250	13	10	24	19	47	39
(1250) - 1600	15	11	29	22	55	44
(1600) - 2000	18	13	35	25	65	51
(2000) - 2500	22	15	41	29	78	59
(2500) - 3150	26	17	50	34	96	69
(3150) - 4000	32	21	62	41	115	82
(4000) - 5000			76	49	140	99
(5000) - 6300					170	119

Lead accuracy control on a complete assembly over one revolution

- l_u = useful travel
- l_e = excess travel (no lead precision required)
- l_o = nominal travel
- l_s = specified travel
- c = travel compensation (difference between l_s and l_o to be defined by the customer, for instance to compensate an expansion)
- e_p = tolerance over the specified travel
- V = travel variation (or permissible band width)
- V_{300p} = maximum permitted travel variation over 300 mm
- V_{up} = maximum permitted travel variation over the useful travel l_u
- V_{300a} = measured travel variation over 300 mm
- V_{ua} = measured travel variation over the useful travel

fig. 1

Case with value of c specified by the customer.

fig. 2

Case with $c = 0$ = standard version in case of no value given by the customer.

fig. 3

Preload adjustment

Cylindrical nuts

In the case of cylindrical nuts (types TRU and PRU for planetary roller screws – type PVU for recirculating roller screws), the threaded housing stoppers must be tightened to the values shown into tables 1 and 2 below. These torques can also be used with one-piece nuts (SRC – BRC – SVC – BVC).

Table 1

SRC/BRC/TRU/PRU

	Housing stopper thread	Tightening torque	Squeeze load
d_0	mm	mN	N
8	30 × 1.0	20	2700
12	35 × 1.0	35	4100
15	40 × 1.0	45	4600
21	50 × 1.0	65	5500
25	60 × 1.0	80	5500
30	70 × 1.5	100	5900
39	90 × 1.5	140	6400
44	88 × 1.5	160	7600
48	110 × 1.5	180	6800
60	130 × 2.0	230	7400
64	125 × 2.0	250	8300
75	158 × 2.0	310	8200
80	148 × 2.0	340	9600
99	215 × 2.5	440	8500
120	230 × 2.5	550	9950
150	340 × 2.5	730	8950

The standard nut is through hardened to 56 → 60 HRC; under some load conditions it is necessary to use hardened & ground spacers (S) to avoid bedding of the nut into the housing & stopper resulting in loss of preload and rigidity.

Table 2

SVC/BVC/PVU

	Housing stopper thread	Tightening torque	Squeeze load

Quality assured

Transrol is certified
ISO 9001/2000 as well as
ISO 14001.
Process running for OHSAS 18001.

Product inspection and certification

Special inspection reports or certificates can be provided and tailored to individual needs on request.

The following are available:

- 1 - Certificate of conformance
- 2 - Lead precision curve
- 3 - Dimensional inspection reports
- 4 - Stiffness curves
- 5 - Magnetic particle inspection
- 6 - Raw material conformity from supplier
- 7 - Chemical analysis
- 8 - Heat treatment
- 9 - Induction hardening
- 10 - Manufacturing & checking list

Service Range

Planetary roller screws with bearing units

Delivery time

1 week
without end machining
2 weeks
with machined ends

Nuts

- ▶ With backlash elimination by oversize rollers: BRC.

Details page 30

Capabilities

- ▶ Machined ends:
 - premachined shafts for machining by the customer
 - to customer drawing (see general rules)
 - suitable for FLRBU units.
- ▶ Screw dimensions: see page 30.

Delivery time

4 weeks
with machined ends
to customer drawing

Nuts

- ▶ With axial play: SRC-SRF
- ▶ With backlash elimination: TRU-TRK
- ▶ Preloaded: PRU-PRK for optimum rigidity.

Details page 32

Capabilities

- ▶ Machined ends to customer drawing (see general rules).
- ▶ Screw dimensions:
 - up to 1500 mm maxi length
 - up to 900 mm threaded length.

GENERAL RULES FOR THE WHOLE SERVICE RANGE

- up to 3 pieces.
- lead precision: G5 to ISO standard.
- standard nuts, standard steel (no special documents such as conformity report).
- lubrication: screw assemblies delivered with machined ends are greased with SKF LGEP2 (temperature range: -20 °C / +120 °C); without end machining, they are only protected with rust inhibitor.

Service Range

Recirculating roller screws with bearing units

Delivery time

1 week
without end machining
2 weeks
with machined ends

Nuts

- ▶ With backlash elimination by oversize rollers: BVC.

Lead 1			
	20	25	32
	Nominal diameter

 - premachined shafts for machining by the customer
 - to customer drawing (see general rules)
 - suitable for FLRBU units
- ▶ Screw dimensions: see page 31

Delivery time

4 weeks
with machined ends
to customer drawing

Nuts

- ▶ With axial play: SVC
- ▶ Preloaded: PVU-PVK for optimum rigidity.

Lead 2					
Lead 1					
	16	20	25	32	40
	Nominal diameter				

Details page 32

Capabilities

- ▶ Machined ends to customer drawing (see general rules)
- ▶ Screw dimensions:
 - up to 1500 mm maxi length
 - up to 900 mm threaded length

RULES (continuation)

- standard machining: no spline, no hollow shaft, no radius in grinding operations. If such any requirements, order cannot be accepted by the Service Channel. Unless specified, tolerances will be according to class 5, ISO 3408-3 (see page 24). FLRBU thrust bearing units can be delivered for all sizes.
- screws for nuclear, aerospace, military or medical applications are excluded.

SKF planetary roller screws

The robust screw for long life in tough conditions has these advantages

- Very high load carrying capacity
- Very long life
- High rotational speed and long lead permit linear speed up to 90 metres/minute
- Planetary timing mechanism permits high acceleration ($> 12\,000 \text{ rad/sec}^2$)
- Robust design to withstand shock loads
- Choice of 3 classes of lead precision
- Planetary timing mechanism ensures correct functioning even in adverse environments such as ice, dirt or poor lubrication
- Special and left hand leads easily available
- Special steels available
- Special surface treatments and lubrication available
- Nut removal without losing rolling elements
- Cylindrical and flanged nuts, with play or preloaded
- Built in wipers available in all cases.

○ Backlash elimination with oversize rollers: as an option under following conditions:

$$\blacktriangleright \frac{\text{total length}}{d_0} \leq 30$$

$$\blacktriangleright \frac{\text{threaded length}}{d_0} \leq 15$$

Cylindrical nuts with axial play, SRC

Backlash elimination with oversize rollers ○ as an option (BRC)

Flanged thrust bearing units

In standard version, the "FLRBU" thrust bearing unit is assembled according to drawing page 30 or 31. If you require a different assembly, please indicate it when ordering.

Flanged bearing unit designation	Angular contact ball bearing (40°)							Lock nut				
	Basic load rating (axial)		Number of bearings	Bearings designation	Maximum preload torque *	Axial rigidity	Tilt rigidity	High precision KMT nut

Undercut l_2 is defined p20.

d_9 can be equal to the root diameter for some sizes.

Other possible bearing arrangement

In case of load acting mainly in one direction, we recommend following thrust bearings.

	C_a (kN)	C_{oa} (kN)	C_a (kN)	C_{oa} (kN)
FLRBU1 (*): No other possible arrangement (1+1)		-	-	-
FLRBU2 (*): No other possible arrangement (1+1)		-	-	-

 Standard program
Right hand lead

 Manufacturing possibilities
on request

SKF recirculating roller screws

The fine screw for ultimate positioning accuracy has these advantages

- 1 mm lead on screws from 8 - 50 mm diameter
- Fine resolution
- Choice of 3 classes of lead precision
- Minimum input torque because of their great mechanical advantage
- Simplification of transmissions to improve their performance
- High load capacity
- Long life
- High rigidity and reliability (no miniaturised parts)
- Special surface treatments and lubrication available
- Cylindrical nuts with play or preloaded
- Preloaded flanged nuts.

○ Backlash elimination with oversize rollers: as an option under following conditions:

$$\blacktriangleright \frac{\text{total length}}{d_1} \leq 30$$

$$\blacktriangleright \frac{\text{threaded length}}{d_1} \leq 15$$

Cylindrical nuts with axial play, SVC

Nuts without wiper recesses

Backlash elimination with oversize rollers $\bigcirc$ as an option (BVC)

Flanged thrust bearing units

In standard version, the "FLRBU" thrust bearing unit is assembled according to drawing page 30 or 31. If you require a different assembly, please indicate it when ordering.

Flanged bearing unit designation	Angular contact ball bearing (40°)							Lock nut				
	Basic load rating (axial)		Number of bearings	Bearings designation	Maximum preload torque *	Axial rigidity	Tilt rigidity	High precision KMT nut

Ultra Power range

The SKF® Ultra Power range is designed for heavy loads and long life.

High load capacities

SKF Ultra Power range of Planetary Roller Screws has been optimised to provide the maximum possible life within a compact space envelope.

This has resulted in an increase in capacity of up to 60 % over the standard product. Load capacity is independent of lead.

To attain L_{10} life performance a mean working load of up to 80 % of C_a is allowed (50 % for HRP/HRC 60). The maximum load should not be applied on the mounting bolts but on the flange.

Designation

HRC: cylindrical nut

HRP: nut with non-central flange

HRF: nut with central flange

® SKF is a registered trademark of SKF.

Short strokes/oscillation performance

The kinematics of all SKF Planetary Roller Screws provides continuous rolling of the working elements without recirculation. This means they are highly reliable in high load applications where there are short strokes and rapid and or many changes of direction.

Axial play

Assemblies are available with an axial play less than 0,1 mm. Preload is not available.

Lead precision

Standard lead precision is G5.

Speed - Environment

All SKF Planetary Roller Screws are rated to a maximum $N \times d_0$ value of 160.000. Their rollers are further controlled by planetary gears which help maintain rolling under extreme condition of speed and/or contamination. The rolling performance provides low noise operation. For maximum speed under heavy load, please contact SKF for advice.

Wipers

Standard version includes wipers (WPR in the designation). Screws can be delivered without wipers on request (NOWPR).

Lubrication

Because of the heavy loads and high duty, special care must be made in the choice of lubricant.

Please contact SKF for advice.

Applications

The "Ultra Power Range" offers the power of hydraulic actuators combined with the precision and flexibility of electric control, for example:

- injection molding machines for plastic and rubber
- presses
- broaching machines
- the steel industry including casting & rolling
- friction welding
- hydro-electric plants
- actuators.

Dynamic and static loads are given for the 15 mm lead.
Root diameter is given for the 15 mm lead.
Outside diameter is given for the maximum lead.

Nota: Roller screw right hand unless specified
If there is a flange on the shaft, please contact SKF.

Nota: Flanges to customer design on request.

Electro-mechanical cylinders

They are designed for long life, high acceleration and high force applications. The cylinders use brushless servomotor technology, with an in-line direct drive as standard.

SKF high performance electro-mechanical cylinders using planetary roller screws are expanding the limits of linear actuators.

The roller screw converts rotary motion into linear movement.

The new Standard for high performance motion

Compact Electro-Mechanical Cylinders (CEMC) are designed to deliver the combination of a dynamic flexible actuation packaged with powerful performance.

Cylinders for heavy loads

High loads and heavy working cycles: long life in adverse environments such as in steel industry.

SKF high efficiency screws are available from:

Calculation formulas

1. Dynamic load rating
(N) and
Basic life rating

$$L_{10} = \left(\frac{C_a}{F_m} \right)^3 \text{ or } C_{\text{req}} = F_m (L_{10})^{1/3}_{\text{req}}$$

L_{10} = life (million of revolutions)
 C_a = basic dynamic load rating
 C_{req} = required dynamic load rating
 F_m = cubic mean load (N)

2. Cubic mean load
(N)

$$F_m = \frac{(F_1^3 L_1 + F_2^3 L_2 + F_3^3 L_3 + \dots)^{1/3}}{(L_1 + L_2 + L_3 + \dots)^{1/3}}$$

$$F_m = \frac{F_{\min} + 2F_{\max}}{3}$$

3. Critical speed of screw shaft
(no safety factor)
(rpm)
(a factor of 0,8 is generally
recommended)

$$n_{\text{cr}} = 490 \cdot 10^5 \cdot \frac{f_1 d_2}{l^2}$$

d_2 = root diameter of the shaft
(mm)
 l = free length, or distance
between the two support bea-
rings (see page 11)

f_1 = 0,9 ●— fixed, free
 3,8 ●—● fixed, supported
 5,6 ●—●— fixed, fixed

4. Speed limit of the mechanism
(maxi speed applied through very
short periods)

$$n \times d_0 < \begin{cases} 30\,000 & \text{for SV/PV } \emptyset \leq 25 \\ < 20\,000 & \text{for SV/PV } \emptyset > 25 \\ < 160\,000 & \text{for SR/TR/PR} \\ & \text{HRC/HRP/HRF} \end{cases}$$

n = revolutions per minute
 d_0 = screw shaft nominal diameter

5. Buckling strength
(with a safety factor: 3)
(N)

$$F_c = \frac{34000 \cdot f_3 \cdot d_2^4}{l^2}$$

d_2 = root diameter (mm)
 l = free length, or distance
between the two support bea-
rings (see page 11)

f_3 = mounting correction factor
 0,25 ●— fixed, free
 1 ●—● supported, supported
 2 ●—● fixed, supported
 4 ●—●— fixed, fixed

6. Theoretical efficiency

- direct
(η)

$$\eta = \frac{1}{1 + \frac{\pi \cdot d_0}{P_h} \mu}$$

- indirect
(η')

$$\eta' = 2 - \frac{1}{\eta}$$

μ = 0,010 for $\emptyset \leq 7^\circ$
 μ = 0,007. $\emptyset$ - 0,04 for $\emptyset > 7^\circ$
 $\emptyset$ = helix angle
 d_0 = nominal diameter of screw
shaft
 P_h = lead (mm)

7. Practical efficiency
(η_p)

$$\eta_p = \eta \cdot 0,9$$

The value 0,9 used is an average
value between the practical effi-
ciency of a new screw and that of a
properly run in screw. It should be
used for industrial applications in all
normal working conditions.
For extreme cases, call us.

Calculation formulas

8. Input torque in a steady state (Nm)

$$T = \frac{F \cdot P_h}{2000 \cdot \pi \cdot \eta_p}$$

F = maximum load of the cycle (N)

9. Power required in a steady state (W)

$$P = \frac{F \cdot n \cdot P_h}{60000 \cdot \eta_p}$$

n = revolutions per minute

10. Preload torque (Nm)

$$T_{pr} = \frac{F_{pr} \cdot P_h}{1000 \cdot \pi} \left(\frac{1}{\eta_p} - 1 \right)$$

F_{pr} = preload (N)

11. Rigidity (N/μm)

$$\frac{1}{R_t} = \frac{1}{R_s} + \frac{1}{R_n}$$

R_n = nut rigidity (see catalogue)

$$R_s = 165 \frac{d_2^2}{l}$$

R_s = screw shaft rigidity (held at one end for standard steel)

$$R_s = \frac{165 d_2^2 l}{l_2 (l - l_2)}$$

R_s = screw shaft rigidity (held at each end, for standard steel)

R_t = total rigidity

l_2 = see page 13

12. Restraining torque (Nm)
(considering system backdriving)

$$T_B = \frac{F \cdot P_h \cdot \eta'}{2000 \cdot \pi}$$

F = load (N)

For safety, we can use the theoretical indirect efficiency

13. Nominal motor torque when accelerating (Nm)

For a horizontal screw

$$T_t = T_f + T_{pr} + \frac{P_h [F + m_L \cdot \mu_f \cdot g]}{2000 \cdot \pi \cdot \eta_p} + \dot{\omega} \Sigma l$$

T_f = torque from friction in support bearings

T_{pr} = preload torque

μ_f = coefficient of friction

η_p = real direct efficiency

$\dot{\omega}$ = angular acceleration (rad/s²)

For a vertical screw

$$T_t = T_f + T_{pr} + \frac{P_h [F + m_L \cdot g]}{2000 \cdot \pi \cdot \eta_p} + \dot{\omega} \Sigma l$$

14. Nominal braking torque when decelerating (Nm)

For a horizontal screw

$$T_t = T_f + T_{pr} + \frac{P_h \cdot \eta' [F + m_L \cdot \mu_f \cdot g]}{2000 \cdot \pi} + \dot{\omega} \Sigma l$$

$\Sigma l = l_M + l_L + l_S \cdot l \cdot 10^{-9}$

$l_L = m_L \left(\frac{P_h}{2\pi} \right)^2 10^{-6}$

η' = theoretical indirect efficiency

For a vertical screw

$$T_t = T_f + T_{pr} + \frac{P_h \cdot \eta' [F + m_L \cdot g]}{2000 \cdot \pi} + \dot{\omega} \Sigma l$$

For additional information, please contact SKF

Symbols

C_{req}	N	Required load rating		c	μm	Travel compensation - the difference between the specified travel and the nominal travel. Its value is always defined by the customer: if not specified it will be assumed to be zero. (The specified travel can also be defined by the specified lead multiplied by the number of revolutions).
C_a	kN	The dynamic load rating (L_{10} life) is such that 90 % of a sufficiently large sample of identical screws can be expected to attain or exceed 1 million revolutions under this constant centrally acting pure axial load without fatigue (flaking).		d_o	mm	Nominal Outside Root Bore] diameter of screw shaft
				d_1	mm	
				d_2	mm	
				d_b	mm	
C_{oa}	kN	The static load rating is that axial constant centrally acting load which produces a total permanent deformation of one raceway and roller of 0,0001 of the diameter of the curved surface of the roller.		e_p	μm	Tolerance of actual mean travel, l_m relative to specified travel l_s
F	N	Axial load		f	-	Factors
F_c	N	Compression load		g	m/s^2	Acceleration of gravity: 9,8
F_m	N	Constant mean axial load		l	mm	Length
F_{pr}	N	The preload force between a nut half (or nut) and the shaft		l_o	mm	Nominal travel - the nominal lead multiplied by the number of revolutions
F_q	N	The squeeze load applied to two nut halves (or nuts) by the housing or fixing bolts		l_1	mm	Threaded length
Hv	-	Vickers hardness		l_e	mm	Excess travel - at each end of the threaded length a distance l_e is subtracted to leave l_u the useful travel. The specified lead precision does not apply to the lengths l_e .
I	kgm^2	Inertia				$l_u = l_1 - 2 l_e$
I_L	kgm^2	Inertia of load				Actual mean travel. The curve is the result of measurements at 20°C of the screw shaft. l_m is the line which fits the curve by the method of least squares
I_M	kgm^2	Inertia of motor		l_m	mm	
I_{nn}	kgm^2	Inertia of nut when turning nut				Specified travel
I_{ns}	kgm^2	Inertia of rollers when turning shaft				Maximum total length
I_s	$kgmm^2/m$	Inertia of screw shaft per metre		l_s	mm	Useful travel - the length of thread which is subject to the specified lead precision
L	10^6 revs	Life		l_{tp}	mm	Mass
L_{10}	10^6 revs	Basic life rating, millions of revolutions		l_u	mm	Mass of the load
L_{10h}	hours	Basic life rating, operating hours				Mass of the nut
M	μm	Maximum difference between mean travels of screws in a matched set		m	kg	Mass of the screw shaft per metre
N	-	Number of thread starts on the screw shaft		m_L	kg	Rotational speed
N_r	-	Standard number of rollers		m_n	kg	Critical speed
N_{max}	-	Maximum number of rollers		m_s	kg/m	Maximum permissible speed
P	watts	Power		n	rpm	Maximum axial play
P_h	mm	Lead		n_{cr}	rpm	Manufacturing tolerance
R	$N/\mu m$	Rigidity		n_p	rpm	Travel variation - the bandwidth or the distance between the two straight lines parallel to the actual mean travel which enclose the curve
R_n	$N/\mu m$	Nut rigidity	including deflection of: • the nut body • rollers/nut contact • rollers/screw shaft contact • length of screw shaft in contact with rollers	s_{ap}	mm	The bandwidth over any 300 mm section of the useful travel. v_{300a} and v_{300p} are actual and permissible values
R_{ng}	$N/\mu m$	Minimum guaranteed nut rigidity		t	μm	The bandwidth over the useful travel. v_{ua} and v_{up} are actual and permissible values
R_{nr}	$N/\mu m$	Reference nut rigidity		v	μm	Deflection
				v_{300}	μm	Helix angle of the screw shaft thread
R_s	$N/\mu m$	Screw shaft rigidity		v_u	μm	Friction angle] $\tan \lambda = \mu$
R_t	$N/\mu m$	Total rigidity				Coefficient of friction
T	Nm	Torque		δ	μm	Coefficient of friction when starting
T_B	Nm	Brake torque		$\emptyset$	$^\circ$	Coefficient of friction for bearing
T_{dt}	Nm	Total torque at constant speed		λ	$^\circ$	Nominal axial stress
T_f	Nm	Torque from friction in support bearings, motor, seals, etc		μ	-	Real axial stress
T_{pe}	Nm	Torque for play elimination		μ_{st}	-	Total stress
T_{pr}	Nm	Preload torque		μ_F	-	Nominal shear stress
T_{st}	Nm	Starting torque		σ	Mpa	Real shear stress
T_t	Nm	Total torque		σ_p	Mpa	Theoretical direct efficiency
U	mm	Stroke length		σ_t	Mpa	Theoretical indirect efficiency
V	hr^{-1}	Strokes per hour	life calculation	τ	Mpa	Real direct efficiency
W	hr/day	Hours per day		τ_p	Mpa	Real indirect efficiency
X	days/year	Days per year		η	-	Angle of twist
Y	years	Years		η'	-	Angular acceleration
Z_s	cc	Grease quantity for screw shaft		η_p	-	Speed quotient, $n_p \times d_o$
Z_n	cc	Grease quantity for nut		η'_p	-	
				θ	$^\circ$	
				$\dot{\omega}$	rad/s^2	
				Ω	$mm \times rpm$	

Designation

	S	R	F	30 x 5R	425/590	G5	L	Z	WPR
Play or preload ?									
S = Axial play (standard range) H = Axial play (Ultra Power range) B = Preload by rollers to eliminate backlash T = Nut preloaded for backlash elimination P = Nut preloaded for optimum rigidity									
Product									
R = Planetary roller screw V = Recirculating roller screw									
Nut type									
C = Cylindrical nut with axial play F = Nut with central flange and axial play P = Nut with non-central flange and axial play U = Preloaded cylindrical nut K = Preloaded nut with central flange									
Nominal diameter x Lead, mm									
Hand									
R = Right L = Left (on request)									
Threaded length / Total length, mm									
Lead precision : G1, G3, G5									
Nut orientation									
(this only applies to flanged nuts SRF, TRK, PRK, PVK, HRP, HRF)									
— = for cylindrical nut S = g6 side of nut towards Shorter machined end L = g6 side of nut towards Longer machined end									
Shaft ends									
Z = to customer's drawing									
Wipers									
WPR = Wipers in the nut : mounted for SR, delivered separately for SVC NOWPR = Without wipers X = Nut without wiper recesses (non standard SR only)
